### Lecture 2 — Review of Processes and Threads

Jeff Zarnett jzarnett@uwaterloo.ca

Department of Electrical and Computer Engineering University of Waterloo

April 25, 2023

ECE 350 Spring 2023 1/37

# Past is Prologue

ECE 350 Spring 2023 2/37

#### The Process

A process is a program in execution.

- 1 The instructions and data.
- **2** The current state.
- 3 Any resources that are needed to execute.

ECE 350 Spring 2023 3/37

### Processes vs. Programs

Note: two instances of the same program running equals two processes.

You may have two windows open for Microsoft Word, and even though they are the same program, they are separate processes.

Similarly, two users who both use Firefox at the same time on a terminal server are interacting with two different processes.

ECE 350 Spring 2023 4/37

### Two Documents, Two Processes

ECE 350 Spring 2023 5/37

#### **Process Control Block**

Data structure for managing processes: Process Control Block (PCB).

It contains everything the OS needs to know about the program.

It is created and updated by the OS for each running process.

It can be thrown away when the program has finished executing and cleaned everything up.

The blocks are held in memory and maintained in some container (e.g., a list) by the kernel.

ECE 350 Spring 2023 6/37

#### **Process Control Block**

#### The process control block will (usually) have:

- Identifier.
- State.
- Priority.
- **■** Program Counter\*.
- Register Data\*.
- Memory Pointers.
- I/O Status Information.
- Accounting Information.

ECE 350 Spring 2023 7/37

# **Process Control Block (Simplified)**

Identifier
State
Priority
Program counter
Memory pointers
Context data
I/O status information
Accounting information
•

ECE 350 Spring 2023 8 / 37

### **Process Control Block**

This data is kept up to date constantly as the process executes.

The program counter and the register data are asterisked.

When the program is running, these values do not need to be updated.

They are needed when a system call (trap) or process switch occurs.

ECE 350 Spring 2023 9 / 37

### **PCB: Asterisked Fields**

We will need a way to restore the state of the program.

Save the state of the process into the PCB.

1. Save the state into the Program Counter variable.

2. Save the Register variables.

ECE 350 Spring 2023 10 / 37

A switch between the execution of process  $P_0$  and process  $P_1$ :

ECE 350 Spring 2023 11/37

#### The Circle of Life

Unlike energy, processes may be created and destroyed.

Upon creation, the OS will create a new PCB for the process. Also initialize the data in that block.

Set: variables to their initial values.

the initial program state.

the instruction pointer to the first instruction in main

Add the PCB to the set.

After the program is terminated and cleaned up: Collect some data (like a summary of accounting information). Remove the PCB from its list of active processes and carry on.

ECE 350 Spring 2023 12 / 37

### **Process Creation**

Three main events that may lead to the creation of a process:

- 1 System boot up.
- 2 User request.
- 3 One process spawns another.

ECE 350 Spring 2023 13 / 37

### **Process Creation: At Boot Up**

When the computer boots up, the OS starts and creates processes.

An embedded system might have all the processes it will ever run.

General-purpose operating systems: allow one (both) of the other ways.

ECE 350 Spring 2023 14/37

### Process Creation: At Boot Up

Some processes will be in the foreground; some in the background.

A user-visible process: log in screen.

Background process: server that shares media on the local network.

UNIX term for a background process is **Daemon**.

Example: ssh (Secure Shell) command to log into a Linux system.

ECE 350 Spring 2023 15 / 37

#### **Process Creation: Users**

Users are well known for starting up processes whenever they feel like it. Much to the chagrin of system designers everywhere.

Every time you double-click an icon or enter a command line command (like ssh above) that will result in the creation of a process.

ECE 350 Spring 2023 16/3

### **Process Creation: Spawning**

An already-executing process may spawn another.

E-mail with a link? Click it; the e-mail program starts the web browser.

A program may break its work up into different logical parts. To promote parallelism or fault tolerance.

The spawning process is the parent and the one spawned is the child.

ECE 350 Spring 2023 17 / 37

### **Process Destruction**

Eventually, most processes die.

This is sad, but it can happen in one of four ways:

- Normal exit (voluntary)
- Error exit (voluntary)
- Fatal Error (involuntary)
- 4 Killed by another process (involuntary)

ECE 350 Spring 2023 18 / 37

#### **Process Destruction: Normal**

Most of the time, the process finishes because they are finished. Or the user asks them to.

Compiler: when compilation is finished, it terminates normally.

You finish writing a document in a text editor, click the close button.

Both examples of normal, voluntary termination.

ECE 350 Spring 2023 19 / 37

#### **Process Destruction: Error**

Sometimes there is voluntary exit, but with an error.

Required write access to the temporary directory & no permission.

Compiler: exit with an error if you ask it to compile a non-existent file.

The program has chosen to terminate because of the error.

ECE 350 Spring 2023 20 / 37

### **Process Destruction: Fatality**

The third reason for termination is a fatal error. Examples: stack overflow, or division by zero.

The OS will detect this error and send it to the program.

Often, this results in involuntary termination of the offending program.

A process may tell the OS it wishes to handle some kinds of errors.

If it can handle it, the process can continue.

Otherwise, unhandled exceptions result in involuntary termination.

ECE 350 Spring 2023 21/37

### **Process Destruction: Killed**

The last reason for termination: one process might be killed by another. (Yes, processes can murder one another. Is no-one safe?!).

Typically this is a user request:

a program is stuck or consuming too much CPU... the user opens task manager (Windows) or ps (UNIX)

Programs can, without user intervention, theoretically kill other processes.

Example: a parent process killing a child it believes to be stuck.

ECE 350 Spring 2023 22 / 37

### **Process Destruction: Killed**

There are restrictions on killing process.

A user or process must have the rights to execute the victim.

Typically a user may only kill a process he or she has created.

Exception: system administrator.

While killing processes may be fun, it is something that should be reserved for when it is needed.

Maybe when a process is killed, all processes it spawned are killed too.

ECE 350 Spring 2023 23 / 37

### **Five State Model**

ECE 350 Spring 2023 24/37

### **Five State Model**

#### There are now eight transitions:

- Create
- Admit
- Dispatch
- Suspend
- Exit
- Block
- Unblock
- Reap

ECE 350 Spring 2023 25 / 37

### **Five State Model**

There are two additional exit transitions that are not shown.

A process can go directly from "Ready" or "Blocked" to "Terminated".

This happens if a process is killed.

ECE 350 Spring 2023 26 / 37

### Seven State Model

ECE 350 Spring 2023 27/37

### Seven State Model

A variant of the five state model.

The "Admit" transition is modified: by default the new process does not start in main memory.

Two new transitions: "Swap In" and "Swap Out".

A second "Unblock" transition.

As in the five state model, some additional "Exit" transitions.

ECE 350 Spring 2023 28 / 37

### **Process Functions**

```
pid_t fork( );
pid_t wait( int* status );
pid_t waitpid( pid_t pid, int *status, int options );
void exit( int status );
```

ECE 350 Spring 2023 29/37

## **Signal Functions**

```
int kill( pid_t pid, int signal );
int raise( int signal );
void ( *signal(int signum, void (*handler)(int)) ) (int);
int pause( );
int sigemptyset( sigset_t* set );
int sigaddset( sigset_t* set, int signal );
int sigdelset( sigset_t* set, int signal );
int sigdelset( sigset_t* set, int signal );
int sigismember( sigset_t* set, int signal );
int sigiprocmask( int how, const sigset_t* set, sigset_t* old_set );
```

ECE 350 Spring 2023 30 / 37

#### What is a Thread?

The term "thread" is a short form of Thread of Execution.

A thread of execution is a sequence of executable commands that can be scheduled to run on the CPU.

Threads also have some state and stores some local variables.

Most programs you will write in other courses have only one thread; that is, your program's code is executed one statement at a time.

ECE 350 Spring 2023 31/37

## **Multithreaded Programs**

A multithreaded program uses more than one thread, (some of the time).

A program begins with an initial thread (where the main method is).

That main thread can create some additional threads if needed.

Threads can be created and destroyed within a program dynamically.

ECE 350 Spring 2023 32 / 37

### **Threads and Processes**

ECE 350 Spring 2023 33 / 37

### **Thread Possessions**

In a process that has multiple threads, each thread has its own:

- 1 Thread execution state.
- 2 Saved thread context when not running.
- 3 Execution stack.
- 4 Local variables.
- 5 Access to the memory and resources of the process (shared with all threads in that process).

ECE 350 Spring 2023 34/37

# Single vs. Multithreaded

single-threaded process

multithreaded process

ECE 350 Spring 2023 35 / 37

#### **Thread Notes**

All the threads of a process share the state and resources of the process.

If a thread opens a file, other threads in that process can also access it.

The way programs are written now, few are not multithreaded.

ECE 350 Spring 2023 36/37

# Why Threads?

Remember there's a performance-risk tradeoff in threads.

If this didn't seem familiar to you, please go back and review ECE 252!

ECE 350 Spring 2023 37/37
