# Lecture 12 — Uniprocessor Scheduling

Jeff Zarnett jzarnett@uwaterloo.ca

Department of Electrical and Computer Engineering University of Waterloo

March 11, 2023

ECE 350 Spring 2023 1/38

# **Uniprocessor Scheduling**

Scheduling is very complex with multiple threads and multiple processors.

To keep things simple, we'll start with one processor.

ECE 350 Spring 2023 2/38

# Scheduling

The basic premise: decide when a process gets to execute.

Four types of scheduling:

- Long-Term Scheduling
- Medium-Term Scheduling
- Short Term Scheduling
- 4 I/O Scheduling (for later)

ECE 350 Spring 2023 3/38

## **Long-Term Scheduling**

The long-term scheduler determines which programs run at all.

How many jobs do we plan to allow concurrently?

Controls the transition from "new" to the "ready state".

ECE 350 Spring 2023 4/38

## **Long-Term Scheduling**

Does not happen much on desktop systems.

The user is responsible for deciding what programs to open.

Sometimes there are per-user limits: e.g, max 100 processes.

Long term example: server-based games (Diablo III) denying a request for a new game due to server load.

Mobile OSes like Android can be more aggressive.

ECE 350 Spring 2023 5/38

## **Medium-Term Scheduling**

More interesting than long-term; related to swapping.

A swapped out process cannot run in the immediate future. But will before too long...

When swapped in, the short term scheduler decides.

ECE 350 Spring 2023 6/38

Sometimes called the dispatcher.

The medium and long term scheduler are all about someday and sometime.

The short term scheduler is about "what are we going to do right now".

The short term scheduler is going to run a lot, so it is very important.

It will often run after certain things occur.

ECE 350 Spring 2023 7/38

Co-operative multitasking, short term scheduling will only take place if:

The currently executing process yields the CPU; or

The currently executing process terminates (voluntarily or with an error).

ECE 350 Spring 2023 8 / 38

This is not how most operating systems work these days.

If the process does yield or terminate, then the short term scheduler will run.

ECE 350 Spring 2023 9/38

What we will discuss from here on out is pre-emptive multitasking.

The operating system, and not the running process, is responsible for deciding when it's time to switch processes.

ECE 350 Spring 2023 10/38

Some pre-emptive systems still have the concept of yield, and that is still an occasion to run the scheduler.

Similarly, in pre-emptive systems, processes still terminate.

ECE 350 Spring 2023 11/38

The dispatcher will certainly run when a process becomes blocked.

Examples: I/O operations (network?), block on mutex, page fault...

ECE 350 Spring 2023 12/38

Another time to make a scheduling decision is after handling an interrupt.

After the interrupt is handled, we can return to execution exactly where we left off, or we can go somewhere else.

The original process is suspended already, so why not leave it in that state?

ECE 350 Spring 2023 13/38

System calls like fork and even signalling on a semaphore may also provide good opportunities to switch from one process to another.

By invoking the operating system (system call), the caller is suspended.

So it is necessary to decide what process executes next.

ECE 350 Spring 2023 14/38

We acknowledged this in the discussion of fork by saying it was not known if the parent or child would execute next.

Semaphores: we do not even know which of the processes waiting on the semaphore will be the one to receive the signal.

Even then, which of the signalling process and waiting process will resume?

ECE 350 Spring 2023 15 / 38

Finally, there is also time slicing.

If time slices are defined as *t* units, every *t* time units, there will be an interrupt generated by the clock.

The interrupt handler runs the short term scheduler to choose a process to run, so that different processes run (seemingly-)concurrently.

ECE 350 Spring 2023 16/

#### **Process Behaviour**

Processes tend to alternate periods of computing with input/output requests.

These tend to alternate; the CPU does a lot of work, called a CPU Burst,

Then some I/O; the period where it is waiting is called the I/O Burst.

After the I/O is completed, the CPU can go at it again.

ECE 350 Spring 2023 17/38

#### **Process Behaviour**

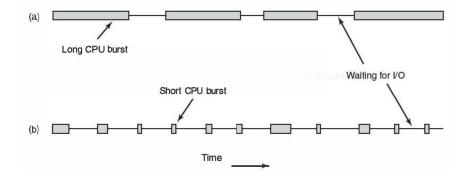

How much of each a process does allows for classification of the process.

Processes that spend most of their time computing are called CPU-Bound.

The alternative is a process that mostly waits for I/O: I/O-Bound

ECE 350 Spring 2023 18 / 38

### CPU- and I/O-Bound Processes

ECE 350 Spring 2023 19 / 38

### CPU- and I/O-Bound Processes

An I/O-Bound program will tend to have short CPU bursts, of course.

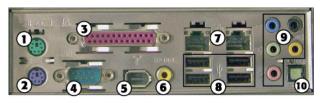

CPUs have gotten faster at a rate much higher than the rate of I/O speedup.

A new CPU comes out every few months and they get faster.

ECE 350 Spring 2023 20/38

#### CPU- and I/O-Bound Processes

I/O standards like Serial-ATA and USB and such change very slowly, over the course of years.

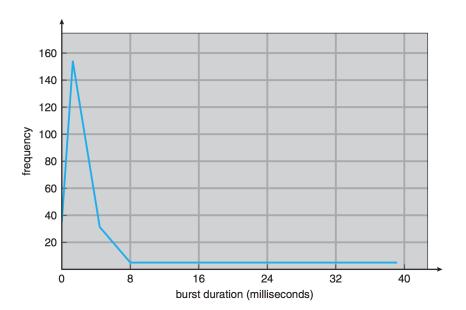

- 1. PS/2 mouse port
- 2. PS/2 keyboard port
- 3. Parallel port
- 4. Serial port
- 5. IEEE 1394a port
- 6. SPDIF coaxial digital audio port
- 7. Ethernet ports
- 8. USB ports
- 9. 1/8-inch mini-jack audio ports
- 10. SPDIF optical digital audio port

So it makes sense that over time programs tend towards being I/O-Bound.

ECE 350 Spring 2023 21/38

# **CPU Burst Histogram**

ECE 350 Spring 2023 22/38

But what does this have to do with scheduling?

The long term scheduler may attempt to keep a balance between CPU- and I/O-Bound tasks to get the best resource utilization.

This requires that the long term scheduler have some idea about which processes are which.

ECE 350 Spring 2023 23/38

#### **Bursts**

Another is that if the disk is slow...

When the disk has nothing to do, the short term scheduler should immediately schedule a process that is likely to issue a disk request.

ECE 350 Spring 2023 24/38

The goals of scheduling depend significantly on the objectives of the system.

First we have to decide what we want.

ECE 350 Spring 2023 25 / 38

If the system is supposed to respond to events within a certain period of time (real time system), this matters a lot to scheduling.

Perhaps the goal is for the CPU to be used maximally (as in a supercomputer).

Or maybe the most important thing is for users to feel like the system answers them quickly when they issue a command.

ECE 350 Spring 2023 26 / 38

As usual when making a decision, we could just decide randomly.

We need evaluation criteria.

ECE 350 Spring 2023 27/38

We will examine and define the following scheduling criteria:

- 1 Turnaround time.
- 2 Response time.
- 3 Deadlines.
- 4 Predictability.
- 5 Throughput.
- 6 Processor utilization.
- 7 Fairness.
- 8 Enforcing priorities.
- 9 Balancing resources.

ECE 350 Spring 2023 28 / 38

# **Scheduling Algorithm Goals**

The priorities of these different goals depend on the kind of system it is.

All Systems:

- Fairness
- Priorities
- Balancing Resources

ECE 350 Spring 2023 29 / 38

# **Scheduling Algorithm Goals**

The priorities of these different goals depend on the kind of system it is.

**Batch Systems:** 

- Throughput
- Turnaround time
- CPU Utilization

ECE 350 Spring 2023 30/38

# **Scheduling Algorithm Goals**

The priorities of these different goals depend on the kind of system it is.

**Interactive Systems:** 

- Response time.
- Predictability.

ECE 350 Spring 2023 31/38

## The (Ab)use of Priorities

Each process's priority is typically an integer.

In UNIX, a lower number is higher priority; Windows is the opposite.

ECE 350 Spring 2023 32/38

### **Priorities**

With a priority value assigned, it can be used to make decisions.

Imagine  $P_1$  wants resource  $R_1$  and  $P_2$  wants that same resource.

If the priority of  $P_1 > P_2$ , choose to assign the resource to  $P_1$ .

ECE 350 Spring 2023 33/38

#### **Priorities**

The OS or the program author may be responsible for assigning a priority.

These priorities may change over time with various criteria.

System administrators can change priorities, usually.

ECE 350 Spring 2023 34/38

#### **Priorities**

Yes, this does mean that some processes are treated better than others. Sometimes solely as the result of inheritance.

ECE 350 Spring 2023 35 / 38

## **User Priority Input**

Users may have a say in priority, in at least a limited way.

In Windows, for example, as a user it may be possible to set a task priority.

Giving this to users was probably a bad idea, because users often do it wrong.

ECE 350 Spring 2023 36 / 38

## **User Priority Input**

If you have a long, CPU-Bound task, the right thing to do is to give it a low priority and not a high one.

You might expect that the high priority will get the task done faster...

It kills the performance of the system and makes users unhappy... Even though that's what they asked for!

ECE 350 Spring 2023 37/38

## **Choosing the Next Process**

In some systems, the highest priority non-blocked process will always run.

This is a great way of making sure that higher priority processes have right-of-way, but a terrible way of ensuring fairness and preventing starvation.

So, scheduling is not as easy as just finding the highest priority thing to do...

ECE 350 Spring 2023 38 / 38
